

LM10506

Triple Buck + LDO Power Management Unit

1.0 General Description

The LM10506 is an advanced PMU containing three configurable, high-efficiency buck regulators for supplying variable voltages. The device is ideal for supporting ASIC and SOC designs for Solid-State and Flash drives.

The LM10506 operates cooperatively with ASIC to optimize the supply voltage for low-power conditions and Power Saving modes via the SPI interface. It also supports a 100 mA LDO and a programmable Interrupt Comparator.

2.0 Key Specifications

- Programmable Buck Regulators:
 - Buck 1: 1.1V to 3.6V; 1.3A
 - Buck 2: 1.1V to 3.6V; 400 mA
 - Buck 3: 0.7V to 1.335V; 600 mA
- $\pm 3\%$ feedback voltage accuracy
- Up to 95% efficient buck regulators
- 2MHz switching frequency for smaller inductor size
- 2.8 x 2.8 mm, 0.4 mm pitch, 34-bump micro SMD package

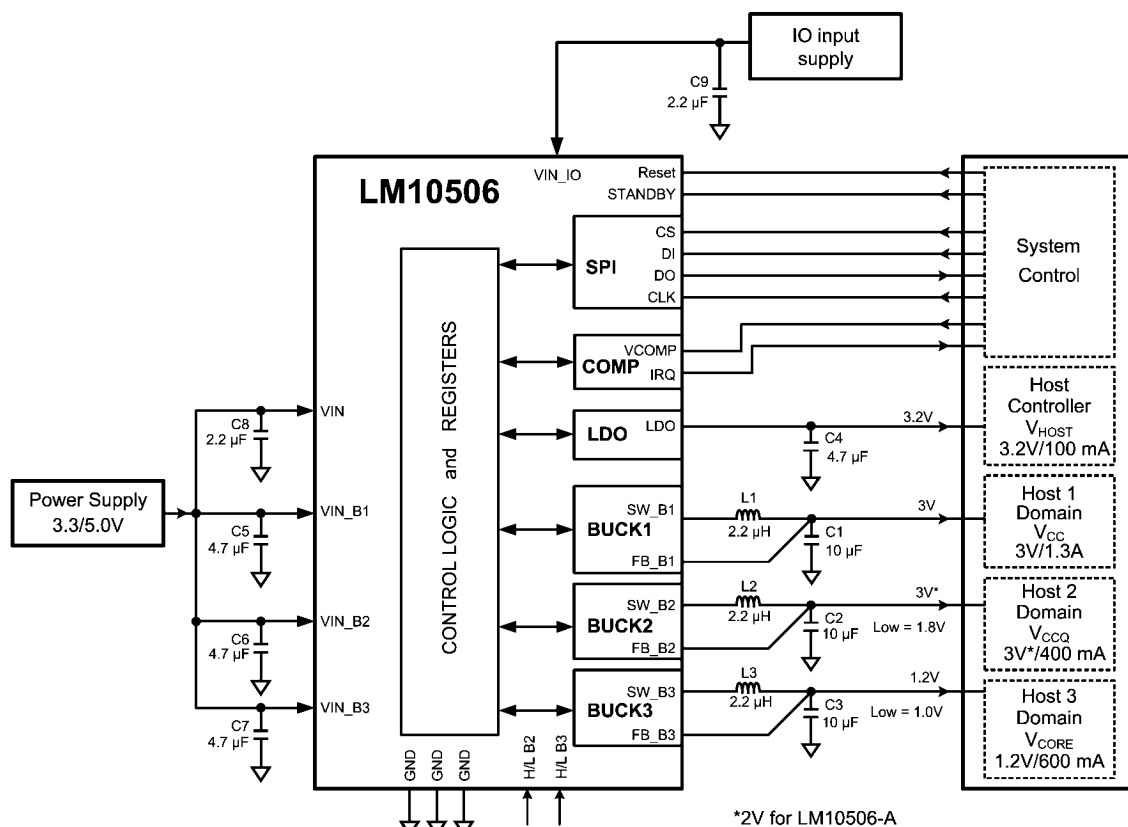

3.0 Features

- Three highly efficient programmable buck regulators
 - Integrated FETs with low $R_{DS(ON)}$
 - Bucks operate with their phases shifted to reduce the input current ripple and capacitor size
 - Programmable Output Voltage via the SPI interface
 - Overvoltage and Undervoltage Lockout
 - Automatic internal soft start with Power-on reset
 - Current overload and thermal shutdown protection
 - Bypass mode available on Bucks 1 and 2
 - PFM mode for low-load, high-efficiency operation
- Low-dropout LDO 3.2V, 100 mA
- SPI-programmable interrupt comparator (2.0V to 4.0V)
- Alternate Buck V_{OUTS} selectable via H/L logic pins
- RESET, STANDBY pins

4.0 Applications

- Solid-State Drives

6.0 Overview

The LM10506 contains three buck converters and one LDO. [Table 1](#) and [Table 2](#) below list the output characteristics of the power regulators. They explain the function of the H/L pins for

B2 and B3 if tied High or Low at startup, and show the part's behavior in standby. The tables also describe the SPI-programmable output voltage range for each buck regulator as well as the maximum output current for the buck regulators and LDO.

6.1 SUPPLY SPECIFICATION

TABLE 1. Output Voltage Configurations for LM10506

Regulator	V _{OUT} if H/L=High (B2, B3)	V _{OUT} if H/L=Low (B2, B3)	V _{OUT} if STANDBY=High (STANDBY Mode)	V _{OUT}	Maximum Output Current	Typical Application	Comments
Buck 1*	3.0V	3.0V	Off	1.1V to 3.6V; 50 mV steps	1.3A	V _{CC}	Flash
Buck 2*	3.0V	1.8V	Off	1.1V to 3.6V; 50 mV steps	400 mA	V _{CCQ}	Interface
Buck 3*	1.2V	1.0V	V _{NOM} - 7%	0.7V to 1.335V; 5mV steps	600 mA	V _{CORE}	Core
LDO	3.2V	3.2V	3.2V	N/A	100 mA	V _{HOST} controller	Reference for Digital

* Default voltage values are determined when working in PWM mode. Voltage may be 0.8-1.6% higher when in PFM mode.

TABLE 2. Output Voltage Configurations for LM10506-A

Regulator	V _{OUT} if H/L=High (B2, B3)	V _{OUT} if H/L=Low (B2, B3)	V _{OUT} if STANDBY=High (STANDBY Mode)	V _{OUT}	Maximum Output Current	Typical Application	Comments
Buck 1*	3.0V	3.0V	Off	1.1V to 3.6V; 50 mV steps	1.3A	V _{CC}	Flash
Buck 2*	2.0V	1.8V	Off	1.1V to 3.6V; 50 mV steps	400 mA	V _{CCQ}	Interface
Buck 3*	1.2V	1.0V	V _{NOM} - 7%	0.7V to 1.335V; 5mV steps	600 mA	V _{CORE}	Core
LDO	3.2V	3.2V	3.2V	N/A	100 mA	V _{HOST} controller	Reference for Digital

* Default voltage values are determined when working in PWM mode. Voltage may be 0.8-1.6% higher when in PFM mode.

Package Mark-Top View

30166219

Note: The actual physical placement of the package marking may vary from part to part. The marking “XY” designates the date code; “TT” is an internal code for die traceability. Both will vary in production. V037 is device identification marking.

8.0 LM10506 Pin Descriptions

Pin #	Pin Name	I/O	Type	Functional Description
A/B5	VIN_B1	I	P	Buck Switcher Regulator 1 - Power supply voltage input for power stage PFET, if Buck 1 is not used, tie to ground to reduce leakage.
A/B6	SW_B1	I/O	P	Buck Switcher Regulator 1 - Power Switching node, connect to inductor
A/B4	FB_B1	I/O	A	Buck Switcher Regulator 1 - Voltage output feedback plus Bypass Power
A/B7	GND_B1	G	P	Buck Switcher Regulator 1 - Power ground for Buck Regulator
G3	VIN_B2	I	P	Buck Switcher Regulator 2 - Power supply voltage input for power stage PFET, if Buck 2 is not used, tie to ground to reduce leakage.
F/G2	SW_B2	I/O	P	Buck Switcher Regulator 2 - Power Switching node, connect to inductor
F3	FB_B2	I	A	Buck Switcher Regulator 2 - Voltage output feedback
G1	GND_B2	G	P	Buck Switcher Regulator 2 - Power ground for Buck Regulator
G5	VIN_B3	I	P	Buck Switcher Regulator 3 - Power supply voltage input for power stage PFET
F/G6	SW_B3	I/O	P	Buck Switcher Regulator 3 - Power Switching node, connect to inductor
F5	FB_B3	I	A	Buck Switcher Regulator 3 - Voltage output feedback
G7	GND_B3	G	P	Buck Switcher Regulator 3 - Power ground for Buck Regulator
A3	VIN	I	P	Power supply Input Voltage, must be present for device to work
A2	LDO	O	P	LDO Regulator - LDO regulator output voltage
G4	HL_B2	I	D	Digital Input Startup Control Signal to change predefined output Voltage of Buck 2, internally pulled down as a default
F4	HL_B3	I	D	Digital Input Startup Control Signal to change predefined output Voltage of Buck 3, internally pulled up as a default
E7	STANDBY	I	D	Digital Input Control Signal for entering Standby Mode. This is an active High pin with an internal pulldown resistor.
F7	RESET	I	D	Digital Input Control Signal to abort SPI transactions; resets the PMIC to default voltages. This is an active Low pin with an internal pullup.
C7	VCOMP	I	A	Analog Input for Comparator
A1	IRQ	O	D	Digital Output of Comparator to signal interrupt condition
F1	SPI_CS	I	D	SPI Interface - chip select
D1	SPI_DI	I	D	SPI Interface - serial data input
E1	SPI_DO	O	D	SPI Interface - serial data output
C1	SPI_CLK	I	D	SPI Interface - serial clock input
B1	VIN_IO	I	A	Supply Voltage for Digital Interface
B2	GND	G	G	Ground. Connect to system Ground.
B3	GND	G	G	Ground. Connect to system Ground.
D7	GND	G	G	Ground. Connect to system Ground.

PSRR	Power Supply Rejection Ratio (Note 2)	F = 10 kHz, $C_{OUT} = 4.7 \mu F$, $I_{OUT} = 20 mA$	$V_{IN} = 5.0V$		65	dB
			$V_{IN} = 3.3V$		40	
$t_{STARTUP}$	Startup Time from Shutdown (Note 2)	$C_{OUT} = 4.7 \mu F$ $I_{OUT} = 100$ mA	$V_{IN} = 5.0V$		45	μs
			$V_{IN} = 3.3V$		60	
$T_{TRANSIENT}$	Startup Transient Overshoot (Note 2)	$C_{OUT} = 4.7 \mu F$ $I_{OUT} = 100 mA$			30	mV

17.0 Comparators Electrical Characteristics (Note 3, Note 4)

Unless otherwise noted, $V_{IN} = 5.0V$ where: $V_{IN} = V_{IN_B1} = V_{IN_B2} = V_{IN_B3}$. Limits appearing in normal type apply for $T_J = 25^\circ C$. Limits appearing in **boldface** type apply over the entire operating junction temperature range of $-40^\circ C \leq T_A = T_J \leq +85^\circ C$.

Symbol	Parameter	Conditions	Min	Typ	Max	Units
I_{VCOMP}	VCOMP pin bias current	$V_{COMP} = 0.0V$		0.1	2	μA
		$V_{COMP} = 5.0V$		0.1	2	
V_{COMP_RISE}	Comparator rising edge trigger level			2.826		V
V_{COMP_FALL}	Comparator falling edge trigger level			2.768		
Hysteresis			30	60	80	mV
IRQ_{VOH}	Output voltage high				$0.8 \cdot V_{IN_IO}$	V
IRQ_{VOL}	Output voltage low		$0.2 \cdot V_{IN_IO}$			
t_{COMP}	Transition time of IRQ output			6	15	μsec

Note 1: Absolute Maximum Ratings are limits beyond which damage to the device may occur. Operating Ratings are conditions under which operation of the device is guaranteed. Operating Ratings do not imply guaranteed performance limits. For guaranteed performance limits and associated test conditions, see the Electrical Characteristics tables.

Note 2: Specification guaranteed by design. Not tested during production.

Note 3: All limits are guaranteed by design, test and/or statistical analysis. All electrical characteristics having room-temperature limits are tested during production with $T_J = 25^\circ\text{C}$. All hot and cold limits are guaranteed by correlating the electrical characteristics to process and temperature variations and applying statistical process control.

Note 4: Capacitors: Low-ESR Surface-Mount Ceramic Capacitors (MLCCs) are used in setting electrical characteristics.

Note 5: Internal thermal shutdown protects device from permanent damage. Thermal shutdown engages at $T_J = +140^\circ\text{C}$ and disengages at $T_J = +120^\circ\text{C}$ (typ.). Thermal shutdown is guaranteed by design.

Note 6: BUCK normal operation is guaranteed if $V_{IN} \geq V_{OUT} + 1.0\text{V}$.

Note 7: In applications where high power dissipation and/or poor thermal resistance is present the maximum ambient temperature may have to be derated. Maximum ambient temperature (T_{A-MAX}) is dependent on the maximum operating junction temperature ($T_{J-MAX-OP} = +125^\circ\text{C}$), the maximum power dissipation of the device in the application (P_{D-MAX}), and the junction-to-ambient thermal resistance of the part/package in the application (θ_{JA}), as given by the following equation:
$$T_{A-MAX} = T_{J-MAX-OP} - (\theta_{JA} \times P_{D-MAX})$$

Note 8: The amount of Absolute Maximum power dissipation allowed for the device depends on the ambient temperature and can be calculated using the formula: $P = (T_J - T_A) / \theta_{JA}$, where T_J is the junction temperature, T_A is the ambient temperature, and θ_{JA} is the junction-to-ambient thermal resistance. θ_{JA} is highly application and board-layout dependent. Internal thermal shutdown circuitry protects the device from permanent damage. (See General Electrical Characteristics.)

18.0 Typical Performance Characteristics

Efficiency of Buck 1: $V_{IN}=5.0V$, $V_{OUT}=3.0V$

19.0 General Description

LM10506 is a highly efficient and integrated Power Management Unit for Systems-on-a-Chip (SoCs), ASICs, and processors. It operates cooperatively and communicates with processors over an SPI interface with output Voltage programmability and Standby Mode.

The device incorporates three high-efficiency synchronous buck regulators and one LDO that deliver four output voltages from a single power source. The device also includes a SPI-programmable Comparator Block that provides an interrupt output signal.

30166204

FIGURE 1. Internal Block Diagram of the LM10506 PMIC

19.1 SPI DATA INTERFACE

The device is programmable via 4-wire SPI Interface. The signals associated with this interface are CS, DI, DO and CLK. Through this interface, the user can enable/disable the device, program the output voltages of the individual Bucks and of course read the status of Flag registers.

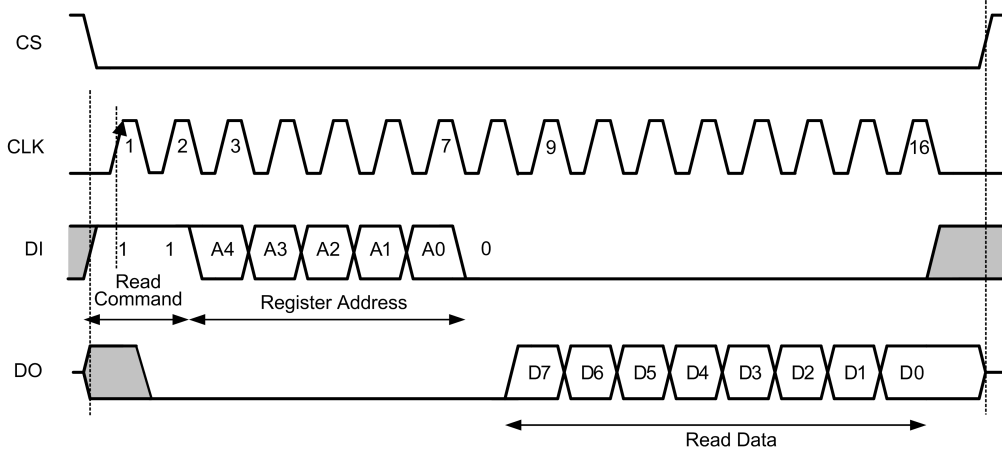

By accessing the registers in the device through this interface, the user can get access and control the operation of the buck controllers and program the reference voltage of the comparator in the device.

19.2 BUCK REGULATORS OPERATION

A buck converter contains a control block, a switching PFET connected between input and output, a synchronous rectify-

ing NFET connected between the output and ground and a feedback path. The following figure shows the block diagram of each of the three buck regulators integrated in the device.

FIGURE 4. Buck Functional Diagram

During the first portion of each switching cycle, the control block turns on the internal PFET switch. This allows current to flow from the input through the inductor to the output filter capacitor and load. The inductor limits the current to a ramp with a slope of $(V_{IN} - V_{OUT})/L$ by storing energy in a magnetic field. During the second portion of each cycle, the control block turns the PFET switch off, blocking current flow from the input, and then turns the NFET synchronous rectifier on. The inductor draws current from ground through the NFET to the output filter capacitor and load, which ramps the inductor current down with a slope of $(-V_{OUT})/L$.

The output filter stores charge when the inductor current is high, and releases it when low, smoothing the voltage across the load. The output voltage is regulated by modulating the PFET switch on time to control the average current sent to the load. The effect is identical to sending a duty-cycle modulated rectangular wave formed by the switch and synchronous rectifier at the SW pin to a low-pass filter formed by the inductor and output filter capacitor. The output voltage is equal to the average voltage at the SW pin.

19.2.1 Buck Regulators Description

The LM10506 incorporates three high-efficiency synchronous switching buck regulators that deliver various voltages from a single DC input voltage. They include many advanced features to achieve excellent voltage regulation, high efficiency and fast transient response time. The bucks feature voltage mode architecture with synchronous rectification.

Each of the switching regulators is specially designed for high-efficiency operation throughout the load range. With a 2MHz typical switching frequency, the external L-C filter can be small and still provide very low output voltage ripple. The bucks are internally compensated to be stable with the recommended external inductors and capacitors as detailed in the application diagram. Synchronous rectification yields high efficiency for low voltage and high output currents.

All bucks can operate up to a 100% duty cycle allowing for the lowest possible input voltage that still maintains the regulation

of the output. The lowest input to output dropout voltage is achieved by keeping the PMOS switch on.

Additional features include soft-start, undervoltage lockout, bypass, and current and thermal overload protection. To reduce the input current ripple, the device employs a control circuit that operates the 3 bucks at 120° phase. These bucks are nearly identical in performance and mode of operation. They can operate in FPWM (forced PWM) or automatic mode (PWM/PFM).

19.2.2 PWM Operation

During PWM operation the converter operates as a voltage-mode controller with input voltage feed forward. This allows the converter to achieve excellent load and line regulation. The DC gain of the power stage is proportional to the input voltage. To eliminate this dependence, a feed forward voltage inversely proportional to the input voltage is introduced.

In **Forced PWM Mode** the bucks always operate in PWM mode regardless of the output current.

In **Automatic Mode**, if the output current is less than 70 mA (typ.), the bucks automatically transition into PFM (Pulse Frequency Modulation) operation to reduce the current consumption. At higher than 100 mA (typ.) they operate in PWM mode. This increases the efficiency at lower output currents. The 30 mA (typ.) hysteresis is designed in for stable Mode transition.

While in PWM mode, the output voltage is regulated by switching at a constant frequency and then modulating the energy per cycle to control power to the load. At the beginning of each clock cycle the PFET switch is turned on, and the inductor current ramps up until the comparator trips and the control logic turns off the switch. The current limit comparator can also turn off the switch in case the current limit of the PFET is exceeded. In this case the NFET switch is turned on and the inductor current ramps down. The next cycle is initiated by the clock turning off the NFET and turning on the PFET.

30166209

FIGURE 5. PFM vs PWM Operation

19.2.3 PFM Operation (Bucks 1, 2 & 3)

At very light loads, Buck 1, 2 and Buck 3 enter PFM mode and operate with reduced switching frequency and supply current to maintain high efficiency.

Buck 1, 2 and 3 will automatically transition into PFM mode when either of two conditions occurs for a duration of 32 or more clock cycles:

1. The inductor current becomes discontinuous, or
2. The peak PMOS switch current drops below the I_{MODE} level.

During PFM operation, the converter positions the output voltage slightly higher than the nominal output voltage during PWM operation, allowing additional headroom for voltage drop during a load transient from light to heavy load. The PFM comparators sense the output voltage via the feedback pin and control the switching of the output FETs such that the output voltage ramps between 0.8% and 1.6% (typical) above the nominal PWM output voltage. If the output voltage is below the 'high' PFM comparator threshold, the PMOS power switch is turned on. It remains on until the output voltage exceeds the 'high' PFM threshold or the peak current exceeds the I_{PFM} level set for PFM mode.

Once the PMOS power switch is turned off, the NMOS power switch is turned on until the inductor current ramps to zero. When the NMOS zero-current condition is detected, the NMOS power switch is turned off. If the output voltage is below the 'high' PFM comparator threshold (see Figure 5), the PMOS switch is again turned on and the cycle is repeated until the output reaches the desired level. Once the output reaches the 'high' PFM threshold, the NMOS switch is turned on briefly to ramp the inductor current to zero and then both output switches are turned off and the part enters an extremely low power mode. Quiescent supply current during this 'idle' mode is less than 100 μA , which allows the part to

achieve high efficiencies under extremely light load conditions. When the output drops below the 'low' PFM threshold, the cycle repeats to restore the output voltage to $\sim 1.6\%$ above the nominal PWM output voltage.

If the load current should increase during PFM mode causing the output voltage to fall below the 'low2' PFM threshold, the part will automatically transition into fixed-frequency PWM mode.

19.2.4 Soft Start

Each of the buck converters has an internal soft-start circuit that limits the in-rush current during startup. This allows the converters to gradually reach the steady-state operating point, thus reducing startup stresses and surges. During startup, the switch current limit is increased in steps.

For **Buck 1, 2 and 3** the soft start is implemented by increasing the switch current limit in steps that are gradually set higher. The startup time depends on the output capacitor size, load current and output voltage. Typical startup time with the recommended output capacitor of 10 μF is 0.2 to 1ms. It is expected that in the final application the load current condition will be more likely in the lower load current range during the start up.

19.2.5 Current Limiting

A current limit feature protects the device and any external components during overload conditions. In PWM mode the current limiting is implemented by using an internal comparator that trips at current levels according to the buck capability. If the output is shorted to ground the device enters a timed current limit mode where the NFET is turned on for a longer duration until the inductor current falls below a low threshold, ensuring inductor current has more time to decay, thereby preventing runaway.

19.2.6 Internal Synchronous Rectification

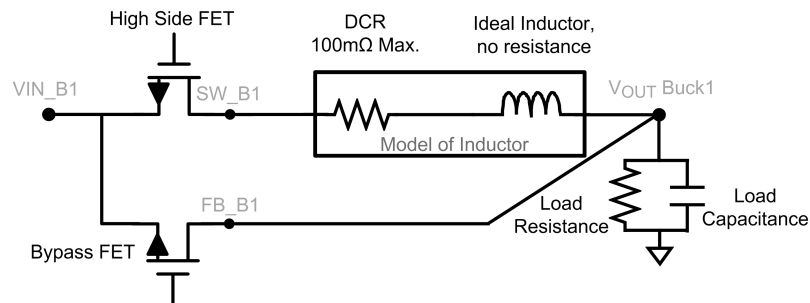

While in PWM mode, the bucks use an internal NFET as a synchronous rectifier to reduce the rectifier forward voltage drop and the associated power loss. Synchronous rectification provides a significant improvement in efficiency whenever the output voltage is relatively low compared to the voltage drop across an ordinary rectifier diode.

19.2.7 Bypass-FET Operation on Buck 1 and Buck 2

There is an additional bypass FET used on Buck 1. The FET is connected in parallel to High Side FET and inductor. Buck 2 has no extra bypass FET – it uses High Side FET (PFET) for bypass operation. If Buck 1 input voltage is greater than 3.5V (2.6V for Buck 2), the bypass function is disabled. The determination of whether or not the Buck regulators are in

bypass mode or standard switching regulation is constantly monitored while the regulators are enabled. If at any time the input voltage goes above 3.5V (2.6V for Buck 2) while in bypass mode, the regulators will transition to normal operation. When the bypass mode is enabled, the output voltage of the buck that is in bypass mode is not regulated, but instead, the output voltage follows the input voltage minus the voltage drop seen across the FET and DCR of the inductor. The voltage drop is a direct result of the current flowing across those resistive elements. When Buck 1 transitions into bypass mode, there is an extra FET used in parallel along with the high side FET for transmission of the current to the load. This added FET will help reduce the resistance seen by the load and decrease the voltage drop. For Buck 2, the bypass function uses the same high side FET.

Equivalent Circuit of Bypass Operation of Buck 1

Equivalent Circuit of Bypass Operation of Buck 2

19.2.8 Low Dropout Operation

The device can operate at 100% duty cycle (no switching; PMOS switch completely on) for low dropout support. In this way the output voltage will be controlled down to the lowest possible input voltage. When the device operates near 100% duty cycle, output voltage ripple is approximately 25 mV.

The minimum input voltage needed to support the output voltage:

$$V_{IN_MIN} = V_{OUT} + I_{LOAD} * (R_{DSON_PFET} + R_{IND}), \text{ where}$$

- I_{LOAD} = Load Current
- R_{DSON_PFET} = Drain to source resistance of PFET (high side) switch in the triode region
- R_{IND} = Inductor resistance

30166212

20.0 Device Operating Modes

20.1 STARTUP SEQUENCE

The startup mode of the LM10506 will depend on the input voltage. Once V_{IN} reaches the UVLO threshold, there is a 15 msec delay before the LM10506 determines how to set up the buck regulators. If V_{IN} is below 3.6V, then Buck 1 and Buck 2 will be in bypass mode, see [Section 19.2.7 Bypass-FET Operation on Buck 1 and Buck 2](#) for functionality description. If the V_{IN} voltage is greater than 3.6V the bucks will start up as the standard regulators. The 3 buck regulators are staggered during startup to avoid large inrush currents. There is a fixed delay of 2 msec between the startup of each regulator.

The Startup Sequence will be:

1. 15 msec ($\pm 30\%$) delay after V_{IN} above UVLO
2. LDO $\rightarrow 3.2V \rightarrow 3.2V$
3. 2 msec delay
4. Buck 1 $\rightarrow 3.0V \rightarrow 3.0V$
5. 2 msec delay
6. Buck 2 $\rightarrow 3.0V$ or if $H/L_B2 = \text{Low} \rightarrow 1.8V$
(For LM10506-A Buck 2 $\rightarrow 2.0V$ or if $H/L_B2 = \text{Low} \rightarrow 1.8V$)
7. 2 msec delay
8. Buck 3 $\rightarrow 1.2V$ or if $H/L_B3 = \text{Low} \rightarrow 1.0V$

30166206

FIGURE 6. Operating Modes

20.2 POWER-ON DEFAULT AND DEVICE ENABLE

The device is always enabled and the LDO is always on, unless outside of operating voltage range. There is no LM10506 Enable Pin. Once V_{IN} reaches a minimum required input Voltage the power-up sequence will be started automatically and the startup sequence will be initiated. Once the device is started, the output voltage of the Bucks 1 and 2 can be individually disabled by accessing their corresponding BKEN register bits (BUCK CONTROL).

20.3 RESET: PIN FUNCTION

The RESET pin is internally pulled high. If the reset pin is pulled low, the device will perform a complete reset of all the registers to their default states. This means that all of the volt-

age settings on the regulators will go back to their default states.

20.4 STANDBY: FUNCTION

The Device can be programmed into Standby mode. There are 2 ways for doing that:

1. STANDBY pin
2. Programming via SPI

20.4.1 STANDBY Pin

When the STANDBY pin is asserted high, the LM10506 will enter Standby Mode. While in Standby Mode, Buck 1 and Buck 2 are disabled. Buck 3's output voltage is transitioned to the PSML (Programmable Standby Mode Level) as set by

register 0x09. The STANDBY pin is internally pulled down, and there is a 1 second delay during powerup before the state of the STANDBY pin is checked. Note: If Buck 1 and Buck 2 are already disabled, and the STANDBY pin is asserted high, then Buck 3 will not go to PSML – for further instructions, see [Section 20.4.2 STANDBY Programming via SPI](#).

Bucks 1 and 2 will be ramped down when the disable signal is given. Buck 1 starts ramping 2ms after Buck 2 has started ramping.

Entering Standby Sequence will be:

1. Buck 3 → PSML (Programmable Standby Mode Level)
2. 2 msec delay
3. Buck 2 → Disabled
4. 2 msec delay
5. Buck 1 → Disabled

An internal 22 kΩ pull down resistor ($\pm 30\%$) is attached to the FB pin of Buck 1 and Buck 2. Buck 1 and 2 outputs are pulled to ground level when they are disabled to discharge any residual charge present in the output circuitry. When STANDBY transitions to a low, Buck 1 is again enabled followed by Buck 2. Buck 3 will go back to its previous state.

When waking up from Standby, the sequence will be:

1. Buck 1 → Previous State
2. 2 msec delay
3. Buck 2 and Buck 3 transition together → Previous State

20.4.2 STANDBY Programming via SPI

There is no bit which has the same function as STANDBY PIN. There is only one requirement programming LM10506 into Standby Mode via SPI. Setting LDO Sleep Mode bit high must be the last move when entering Standby Mode and programming the bit low when waking from Standby Mode must be the first move. Disabling or programming the Bucks to new level is the user's decision based on power consumption and other requirements.

The following section describes how to program the chip into Standby Mode corresponding to STANDBY PIN function. To program the LM10506 to Standby Mode via SPI Buck 1 and Buck 2 must be disabled by host device (Register 0x0A bit 1 and 0). Buck 3 must be programmed to desired level using Register 0x00. After Buck 3 has finished ramping LDO Sleep Mode bit must be set high (Register 0x0E bit 1). To wake LM10506 from Standby Mode LDO Sleep Mode bit must be set low (Register 0x0E bit 1). Buck 1 and 2 must be enabled. Buck 3 voltage must be programmed to previous output level.

20.5 HL_B2, HL_B3 FUNCTION

The HL_B2/3 pins are digital pins which control alternate voltage selections of Buck 2 and Buck 3, respectively. HL_B2 has an internal pulldown which defaults to a 1.8V output voltage selection for Buck 2. Alternatively, if HL_B2 is driven high, an output voltage of 3.0V (or 2.0V for LM10506-A) is selected. HL_B3 has an internal pullup which defaults to a 1.2V output voltage selection for Buck 3. Alternatively, if HL_B3 is driven low, an output voltage of 1.0V is selected. The pullup resistor is connected to the main input voltage. Transitions of the pins will not affect the output voltage, the state is only checked during startup.

20.6 UNDERVOLTAGE LOCKOUT (UVLO)

The V_{IN} voltage is monitored for a supply under voltage condition, for which the operation of the device can not be guaranteed. The part will automatically disable Buck 3. To prevent

unstable operation, the undervoltage lockout (UVLO) has a hysteresis window of about 300 mV. An UVLO will force the device into the reset state, all internal registers are reset. Once the supply voltage is above the UVLO hysteresis, the device will initiate a power-up sequence and then enter the active state.

Buck 1 and Buck 2 will remain in bypass mode after V_{IN} passes the UVLO until V_{IN} reaches approximately 1.9V. When Buck 2 is set to 1.8V, the voltage will jump from 1.8V to $V_{UVLO_FALLING}$, and then follow V_{IN} .

The LDO and the Comparator will remain functional past the UVLO threshold until V_{IN} reaches approximately 2.25V.

20.7 OVERVOLTAGE LOCKOUT (OVLO)

The V_{IN} voltage is monitored for a supply over voltage condition, for which the operation of the device cannot be guaranteed. The purpose of overvoltage lockout (OVLO) is to protect the part and all other consumers connected to the PMU outputs from any damage and malfunction. Once V_{IN} rises over 5.7V all the Bucks, and LDO will be disabled automatically. To prevent unstable operation, the OVLO has a hysteresis window of about 100 mV. An OVLO will force the device into the reset state; all internal registers are reset. Once the supply voltage is below the OVLO hysteresis, the device will initiate a power-up sequence, and then enter the active state. Operating maximum input voltage at which parameters are guaranteed is 5.5V. Absolute maximum of the device is 6.0V.

20.8 DEVICE STATUS, INTERRUPT ENABLE

The LM10506 has 2 interrupt registers, INTERRUPT ENABLE and INTERRUPT STATUS. These registers can be read via the serial interface. The interrupts are not latched to the register and will always represent the current state and will not be cleared on a read.

If interrupt condition is detected, then corresponding bit in the INTERRUPT STATUS register (0x0D) is set to '1', and IRQ output is asserted. There are 5 interrupt generating conditions:

- Buck 3 output is over flag level (90% when rising, 85% when falling)
- Buck 2 output is over flag level (90% when rising, 85% when falling)
- Buck 1 output is over flag level (90% when rising, 85% when falling)
- LDO is over flag level (90% when rising, 85% when falling)
- Comparator input voltage crosses over selected threshold

Reading the interrupt register will not release IRQ output. Interrupt generation conditions can be individually enabled or disabled by writing respective bits in INTERRUPT ENABLE register (0x0C) to '1' or '0'.

20.9 THERMAL SHUTDOWN (TSD)

The temperature of the silicon die is monitored for an over-temperature condition, for which the operation of the device can not be guaranteed. The part will automatically be disabled if the temperature is too high. The thermal shutdown (TSD) will force the device into the reset state. In reset, all circuitry is disabled. To prevent unstable operation, the TSD has a hysteresis window of about 20°C. Once the temperature has decreased below the TSD hysteresis, the device will initiate a powerup sequence and then enter the active state. In the active state, the part will start up as if for the first time, all registers will be in their default state.

20.10 COMPARATOR

The comparator on the LM10506 takes its inputs from the VCOMP pin and an internal threshold level which is programmed by the user. The threshold level is programmable between 2.0 and 4.0V with a step of 31 mV and a default comp code of 0x19. The output of the comparator is the IRQ pin. Its polarity can be changed using Register 0x0E bit 0. If IRQ_polarity = 0 → Active low (default) is selected, then the output is low if V_{COMP} value is greater than the threshold level. The

output is high if the V_{COMP} value is less than the threshold level. If IRQ_polarity = 1 → Active high is selected then the output is high if V_{COMP} value is greater than the threshold level. The output is low if the V_{COMP} value is less than the threshold level. There is some hysteresis when V_{COMP} transitions from high to low, typically 60 mV. There is a control bit in register 0x0B, comparator control, that can double the hysteresis value.

21.0 External Components Selection

All three switchers require an input capacitor and an output inductor-capacitor filter. These components are critical to the performance of the device. All three switchers are internally compensated and do not require external components to achieve stable operation. The output voltages of the bucks can be programmed through the SPI pins.

21.1 OUTPUT INDUCTORS & CAPACITORS SELECTION

There are several design considerations related to the selection of output inductors and capacitors:

- Load transient response
- Stability
- Efficiency
- Output ripple voltage
- Over current ruggedness

The device has been optimized for use with nominal LC values as shown in the Typical Application Circuit (page 1).

21.2 INDUCTOR SELECTION

The recommended inductor values are shown in [Section 5.0 Typical Application Diagram](#). It is important to guarantee the inductor core does not saturate during any foreseeable operational situation. The inductor should be rated to handle the peak load current plus the ripple current:

Care should be taken when reviewing the different saturation current ratings that are specified by different manufacturers. Saturation current ratings are typically specified at 25°C, so ratings at maximum ambient temperature of the application should be requested from the manufacturer.

$$\begin{aligned} I_{L(\text{MAX})} &= I_{\text{LOAD}(\text{MAX})} + \Delta I_{\text{RIPPLE}} \\ &= I_{\text{LOAD}(\text{MAX})} + \frac{D \times (V_{\text{IN}} - V_{\text{OUT}})}{2 \times L \times F_{\text{S}}} \\ &\approx I_{\text{LOAD}(\text{MAX})} + \frac{D \times (V_{\text{IN}} - V_{\text{OUT}})}{2 \times 2.2 \times 2.0} \text{ (A typ.)}, \\ D &= \frac{V_{\text{OUT}}}{V_{\text{IN}}}, F_{\text{S}} = 2 \text{ MHz}, L = 2.2 \mu\text{H} \end{aligned}$$

There are two methods to choose the inductor saturation current rating:

21.2.1 Recommended Method for Inductor Selection:

The best way to guarantee the inductor does not saturate is to choose an inductor that has saturation current rating greater than the maximum device current limit, as specified in the Electrical Characteristics tables. In this case the device will prevent inductor saturation by going into current limit before the saturation level is reached.

21.2.2 Alternate Method for Inductor Selection:

If the recommended approach cannot be used care must be taken to guarantee that the saturation current is greater than the peak inductor current:

$$\begin{aligned} I_{\text{SAT}} &> I_{\text{LPEAK}} \\ I_{\text{LPEAK}} &= I_{\text{OUTMAX}} + \frac{I_{\text{RIPPLE}}}{2} \\ I_{\text{RIPPLE}} &= \frac{D \times (V_{\text{IN}} - V_{\text{OUT}})}{L \times F_{\text{S}}} \\ D &= \frac{V_{\text{OUT}}}{V_{\text{IN}} \times \text{EFF}} \end{aligned}$$

I_{SAT} :	Inductor saturation current at operating temperature
I_{LPEAK} :	Peak inductor current during worst case conditions
I_{OUTMAX} :	Maximum average inductor current
I_{RIPPLE} :	Peak-to-Peak inductor current
V_{OUT} :	Output voltage
V_{IN} :	Input voltage
L:	Inductor value in Henries at I_{OUTMAX}
F:	Switching frequency, Hertz
D:	Estimated duty factor
EFF:	Estimated power supply efficiency

I_{SAT} may not be exceeded during any operation, including transients, startup, high temperature, worst-case conditions, etc.

21.2.2.1 Suggested Inductors and Their Suppliers

The designer should choose the inductors that best match the system requirements. A very wide range of inductors are available as regarding physical size, height, maximum current (thermally limited, and inductance loss limited), series resistance, maximum operating frequency, losses, etc. In general, smaller physical size inductors will have higher series resistance (DCR) and implicitly lower overall efficiency is achieved. Very low-profile inductors may have even higher series resistance. The designer should try to find the best compromise between system performance and cost.

TABLE 3. Recommended Inductors

Value	Manufacturer	Part Number	DCR	Current	Package
2.2 μH	Murata	LQH55PN2R2NR0L	31 m Ω	2.5A	2220
2.2 μH	TDK	NLC565050T-2R2K-PF	60 m Ω	1.3A	2220
2.2 μH	Murata	LQM2MPN2R2NG0	110 m Ω	1.2A	806

21.2.3 OUTPUT AND INPUT CAPACITORS CHARACTERISTICS

Special attention should be paid when selecting these components. As shown in the following figure, the DC bias of these capacitors can result in a capacitance value that falls below the minimum value given in the recommended capacitor specifications table. Note that the graph shows the capacitance out of spec for the 0402 case size capacitor at higher bias voltages. It is therefore recommended that the capacitor manufacturers' specifications for the nominal value capacitor are consulted for all conditions, as some capacitor sizes (e.g., 0402) may not be suitable in the actual application.

FIGURE 7. Typical Variation in Capacitance vs. DC Bias

The ceramic capacitor's capacitance can vary with temperature. The capacitor type X7R, which operates over a temperature range of -55°C to $+125^{\circ}\text{C}$, will only vary the capacitance to within $\pm 15\%$. The capacitor type X5R has a similar tolerance over a reduced temperature range of -55°C to $+85^{\circ}\text{C}$. Many large value ceramic capacitors, larger than $1\mu\text{F}$ are manufactured with Z5U or Y5V temperature characteristics. Their capacitance can drop by more than 50% as the temperature varies from 25°C to 85°C . Therefore X7R is recommended over Z5U and Y5V in applications where the ambient temperature will change significantly above or below 25°C .

Tantalum capacitors are less desirable than ceramic for use as output capacitors because they are more expensive when comparing equivalent capacitance and voltage ratings in the

$0.47\mu\text{F}$ to $44\mu\text{F}$ range. Another important consideration is that tantalum capacitors have higher ESR values than equivalent size ceramics. This means that while it may be possible to find a tantalum capacitor with an ESR value within the stable range, it would have to be larger in capacitance (which means bigger and more costly) than a ceramic capacitor with the same ESR value. It should also be noted that the ESR of a typical tantalum will increase about 2:1 as the temperature goes from 25°C down to -40°C , so some guard band must be allowed.

21.2.3.1 Output Capacitor Selection

The output capacitor of a switching converter absorbs the AC ripple current from the inductor and provides the initial response to a load transient. The ripple voltage at the output of the converter is the product of the ripple current flowing through the output capacitor and the impedance of the capacitor. The impedance of the capacitor can be dominated by capacitive, resistive, or inductive elements within the capacitor, depending on the frequency of the ripple current. Ceramic capacitors have very low ESR and remain capacitive up to high frequencies. Their inductive component can usually be neglected at the frequency ranges at which the switcher operates.

30166216

The output-filter capacitor smooths out the current flow from the inductor to the load and helps maintain a steady output voltage during transient load changes. It also reduces output voltage ripple. These capacitors must be selected with sufficient capacitance and low enough ESR to perform these functions.

Note that the output voltage ripple increases with the inductor current ripple and the Equivalent Series Resistance of the output capacitor (ESR_{COUT}). Also note that the actual value of the capacitor's ESR_{COUT} is frequency and temperature dependent, as specified by its manufacturer. The ESR should be calculated at the applicable switching frequency and ambient temperature.

$$V_{\text{OUT-RIPPLE-PP}} = \frac{\Delta I_{\text{RIPPLE}}}{8 \times F_s \times C_{\text{OUT}}} \quad \text{where } \Delta I_{\text{RIPPLE}} = \frac{D \times (V_{\text{IN}} - V_{\text{OUT}})}{2 \times L \times F_s} \quad \text{and } D = \frac{V_{\text{OUT}}}{V_{\text{IN}}}$$

30166217

Output ripple can be estimated from the vector sum of the reactive (capacitance) voltage component and the real (ESR) voltage component of the output capacitor where:

$$V_{\text{OUT-RIPPLE-PP}} = \sqrt{V_{\text{ROUT}}^2 + V_{\text{COUT}}^2}$$

where:

$$V_{\text{ROUT}} = I_{\text{RIPPLE}} \times \text{ESR}_{\text{COUT}} \text{ and } V_{\text{COUT}} = \frac{I_{\text{RIPPLE}}}{8 \times F_{\text{S}} \times C_{\text{OUT}}}$$

$V_{\text{OUT-RIPPLE-PP}}$: estimated output ripple,
 V_{ROUT} : estimated real output ripple,
 V_{COUT} : estimated reactive output ripple.

TABLE 4. Recommended Output Capacitors

Model	Type Vendor	Vendor	Voltage Rating	Case Size
08056D226MAT2A	Ceramic, X5R	AVX Corporation	6.3V	0805, (2012)

JMK212BJ226MG-T	Ceramic, X5R	Taiyo Yuden	6.3V	0603, (1608)
C2012X5R0J226M	Ceramic, X5R	TDK Corporation	6.3V	0603, (1608)

21.2.3.2 Input Capacitor Selection

There are 3 buck regulators in the LM10506 device. Each of these buck regulators has its own input capacitor which should be located as close as possible to their corresponding SW_x_VIN and SW_x_GND pins, where x designates Buck 1, 2 or 3. The 3 buck regulators operate at 120° out of phase, which means that they switch on at equally spaced intervals, in order to reduce the input power rail ripple. It is recommended to connect all the supply/ground pins of the buck regulators, SW_x_VIN to two solid internal planes located under the device. In this way, the 3 input capacitors work together and further reduce the input current ripple. A larger tantalum capacitor can also be located in the proximity of the device.

The input capacitor supplies the AC switching current drawn from the switching action of the internal power FETs. The input current of a buck converter is discontinuous, so the ripple current supplied by the input capacitor is large. The input capacitor must be rated to handle both the RMS current and the dissipated power.

The input capacitor must be rated to handle this current:

$$I_{\text{RMS_CIN}} = I_{\text{OUT}} \frac{\sqrt{V_{\text{OUT}} (V_{\text{IN}} - V_{\text{OUT}})}}{V_{\text{IN}}}$$

The power dissipated in the input capacitor is given by:

$$P_{\text{D_CIN}} = I_{\text{RMS_CIN}}^2 \times R_{\text{ESR_CIN}}$$

The device is designed to be used with ceramic capacitors on the inputs of the buck regulators. The recommended dielectric type of these capacitors is X5R, X7R, or of comparable material to maintain proper tolerances over voltage and temperature. The minimum recommended value for the input

The device is designed to be used with ceramic capacitors on the outputs of the buck regulators. The recommended dielectric type of these capacitors is X5R, X7R, or of comparable material to maintain proper tolerances over voltage and temperature. The recommended value for the output capacitors is 22 μF, 6.3V with an ESR of 2mΩ or less. The output capacitors need to be mounted as close as possible to the output/ground pins of the device.

capacitor is 10 μF with an ESR of 10 mΩ or less. The input capacitors need to be mounted as close as possible to the power/ground input pins of the device.

The input power source supplies the average current continuously. During the PFET switch on-time, however, the demanded di/dt is higher than can be typically supplied by the input power source. This delta is supplied by the input capacitor.

A simplified “worst case” assumption is that all of the PFET current is supplied by the input capacitor. This will result in conservative estimates of input ripple voltage and capacitor RMS current.

Input ripple voltage is estimated as follows:

$$V_{\text{PPIN}} = \frac{I_{\text{OUT}} \times D}{C_{\text{IN}} \times F_{\text{S}}} + I_{\text{OUT}} \times \text{ESR}_{\text{CIN}}$$

where:

V_{PPIN} : estimated peak-to-peak input ripple voltage,
 I_{OUT} : Output Current
 C_{IN} : Input capacitor value
 ESR_{CIN} : input capacitor ESR.

This capacitor is exposed to significant RMS current, so it is important to select a capacitor with an adequate RMS current rating. Capacitor RMS current estimated as follows:

$$I_{\text{RMSCIN}} = \sqrt{D \times \left(I_{\text{OUT}}^2 + \frac{I_{\text{RIPPLE}}^2}{12} \right)}$$

I_{RMSCIN} : estimated input capacitor RMS current.

22.0 PCB Layout Considerations

PC board layout is an important part of DC-DC converter design. Poor board layout can disrupt the performance of a DC-DC converter and surrounding circuitry by contributing to EMI,

ground bounce, and resistive voltage loss in the traces. These can send erroneous signals to the DC-DC converter resulting in poor regulation or instability. Good layout can be implemented by following a few simple design rules.

30166225

FIGURE 8. Schematic of LM10506 Highlighting Layout Sensitive Nodes

1. Minimize area of switched current loops. In a buck regulator there are two loops where currents are switched rapidly. The first loop starts from the C_{IN} input capacitor, to the regulator SW_x_VIN pin, to the regulator SW pin, to the inductor then out to the output capacitor C_{OUT} and load. The second loop starts from the output capacitor ground, to the regulator SW_x_GND pins, to the inductor and then out to C_{OUT} and the load (see figure above). To minimize both loop areas the input capacitor should be placed as close as possible to the VIN pin. Grounding for both the input and output capacitors should consist of a small localized top side plane that connects to PGND. The inductor should be placed as close as possible to the SW pin and output capacitor.
2. Minimize the copper area of the switch node. The SW pins should be directly connected with a trace that runs on top side directly to the inductor. To minimize IR losses this trace should be as short as possible and with a sufficient width. However, a trace that is wider than 100 mils will increase the copper area and cause too much capacitive loading on the SW pin. The inductors should be placed as close as possible to the SW pins to further minimize the copper area of the switch node.
3. Have a single point ground for all device analog grounds. The ground connections for the feedback components should be connected together then routed to the GND pin of the device. This prevents any switched or load currents from flowing in the analog ground plane. If not properly handled, poor grounding can result in degraded load regulation or erratic switching behavior.
4. Minimize trace length to the FB pin. The feedback trace should be routed away from the SW pin and inductor to avoid contaminating the feedback signal with switch noise.
5. Make input and output bus connections as wide as possible. This reduces any voltage drops on the input or output of the converter and can improve efficiency. If voltage accuracy at the load is important make sure feedback voltage sense is made at the load. Doing so will correct for voltage drops at the load and provide the best output accuracy.

22.1 PCB LAYOUT THERMAL DISSIPATION FOR MICRO SMD PACKAGE

1. Position ground layer as close as possible to micro SMD package. Second PCB layer is usually good option. LM10506 evaluation board is a good example.
2. Draw power traces as wide as possible. Bumps which carry high currents should be connected to wide traces. This helps the silicon to cool down.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
